Final Exam

Please answer all four questions. Each question carries 25% of the total grade.

1. Explain the reasons why you agree or disagree with the following statements. Circle the correct answer and use the space to justify your choice.

(i) It is never optimal to exercise an American put option prior to its expiration date.  
*Agree / Disagree, because*

(ii) European put-call parity states that the cost of buying a call and a put option equals the price of the underlying stock.  
*Agree / Disagree, because*

(iii) Implied volatility can be backed out of existing option prices. It shows how volatile the market expects future stock price movements to be.  
*Agree / Disagree, because*
(iv) An investor who has sold a call option and is hedging this position needs to buy more shares if the underlying stock price goes up.

Agree / Disagree, because

(v) The delta of a European put option lies between minus one and zero. It increases when the stock price goes up.

Agree / Disagree, because

(vi) Pricing of options in the binomial tree only works if investors are risk-neutral.

Agree / Disagree, because
2. The following binomial diagram gives a company's stock price at three points in time:

```
  144
  120
 100
  80
```

The risk-free interest rate is $\ln(1.06)$ per period. Each period is one year; $u$ is 1.20 and $d$ is 0.80. The stock pays no dividends prior to period 2.

(i) What is the risk-neutral probability?

$p =$

(ii) At each node in the tree, calculate the price of an American call with a strike price of 90 and expiration at time 2.

$$C_{uu} =$$

$$C_u =$$

$$C =$$

$$C_d =$$

$$C_{dd} =$$

$$t=0$$ $$t=1$$ $$t=2$$

(iii) What would be the value of the call option at time 0, if it had been a European rather than an American call option?

$$c \text{ (European)} =$$
(iv) At each node of the tree, compute the price of an American put option with a strike price of 100 and expiration at time 2.

\[
P_{uu} = \\
P_u = \\
P = \\
P_d = \\
P_{dd} = \\
\]

t=0 \quad t=1 \quad t=2

(v) At the nodes at time 0 and 1, compute the American put option’s delta

\[
\Delta_u = \\
\Delta = \\
\Delta_d = \\
\]

\[
t = 0 \quad t = 1
\]

(v) Suppose you have sold a put option at time 0 and wish to set up a perfect hedge for the next period. How could you do this by trading the underlying stock? (give the relevant number of shares and explain if you would buy or sell the shares)
3. A company's reported stock price over the last six trading days were as follows (moving from the earliest to the last price):

\[50 \ 51 \ 51 \ 52 \ 51 \ 50\]

The stock price closed at 50. This volatility is typical of expected future volatility. Currently the continuously compounded interest rate is \(\ln(1.06)\). The stock will not pay any dividends over the next 30 days.

**Black-Scholes Formula**

\[
c = S_0N(d_1) - Xe^{-rT}N(d_2), \quad p = Xe^{-rT}N(-d_2) - S_0N(-d_1),
\]

\[
d_1 = \frac{\ln(S_0/X) + (r + \frac{s^2}{2})T}{s\sqrt{T}}, \quad d_2 = d_1 - s\sqrt{T}.
\]

(i) Use Black-Scholes to find the value of a European call option with 30 (trading) days to expiration and a strike price of 48.

Volatility estimate: \(\sigma = \)

\[
d_1 = \quad N(d_1) =
\]

\[
d_2 = \quad N(d_2) =
\]

BS call price =

(ii) What is the value of a European put option with 30 (trading) days to expiration and a strike price of 48?

\[
N(-d_2) = \quad N(-d_1) =
\]

BS put price =
(iii) Compute the delta of the Black-Scholes call option

\[
\text{Call delta} =
\]

(iv) Explain what this delta measures

(iii) If the stock price, \( S_0 \), gets very large, what are the Black-Scholes values of the call and put options?

\[
\text{Call} =
\]

\[
\text{Put} =
\]
4. On Friday November 17, 2000 Compaq’s stock price closed at 25. The following option prices were quoted in WSJ:

<table>
<thead>
<tr>
<th>Strike</th>
<th>Expiration</th>
<th>Call Price</th>
<th>Put Price</th>
</tr>
</thead>
<tbody>
<tr>
<td>22.50</td>
<td>Dec</td>
<td>3.30</td>
<td>0.90</td>
</tr>
<tr>
<td>25</td>
<td>Dec</td>
<td>1.85</td>
<td>1.80</td>
</tr>
<tr>
<td>27.50</td>
<td>Dec</td>
<td>0.85</td>
<td>3.20</td>
</tr>
<tr>
<td>30</td>
<td>Dec</td>
<td>0.35</td>
<td>5.40</td>
</tr>
</tbody>
</table>

(i) Plot the profit diagram for a short position in a December *straddle* with a strike price of 25 as a function of the stock price at expiration and fill in the requested information.

Maximum profit:

Maximum loss:

(ii) Plot the profit diagram (at expiration) for a *bull* spread based on the December call options with strike prices 25 and 30.

Range of stock prices at expiration with a positive profit:
(iii) Show the profit (at expiration) from an investment that buys the *stock* and sells the December *call* option with a strike price of 27.50.

Maximum profit:

Break-even point:

(iv) Plot the profit diagram (at expiration) for a *butterfly* spread based on the call options with strike prices of 22.50, 25 and 27.50.

Maximum loss:

Maximum profit:
