

Uncovering Disaggregated Oil Market Dynamics: A Full- Information Approach to Granular Instrumental Variables

Christiane Baumeister, University of Notre Dame

James D. Hamilton, UCSD

Paper's contributions

- Estimate dynamic model of world oil supply and demand
- Provide integrated estimates of individual country elasticities with global outcomes
- Develop new approach to identification and efficient estimation
- Illustrate counterfactual simulations such as dynamic consequences of exogenous disruption in Russian oil production

Data

Data from 1973:M1 to 2023:M2 (drop COVID)

q_{it} = growth rate of country i oil production

s_{qi} = share of country i in world total

$\sum_{i=1}^n s_{qi} q_{it}$ = approximate growth in global oil production

Our empirical analysis will use the three biggest producers (U.S., Saudi Arabia, Russia) plus the rest of the world ($n = 4$)

c_{jt} = growth rate of country j oil consumption

s_{cj} = share of country j in world total

$\sum_{j=1}^m s_{cj} c_{jt}$ = approximate growth in global oil consumption

Our empirical analysis will use the three biggest historical consumers (U.S., Japan, Europe) plus the rest of the world ($m = 4$)

Supply curve of country i

$$q_{it} = \phi_{qi} p_t + \mathbf{b}'_{qi} \mathbf{X}_{t-1} + u_{qit}$$

ϕ_{qi} = country i short-run supply elasticity

$\mathbf{X}_{t-1}$ contains intercept, 12 lags production and consumption of every country in world, and 12 lags of world price

u_{qit} = supply shock for country i

$$q_{it} = \phi_{qi} p_t + \mathbf{b}_{qi}' \mathbf{x}_{t-1} + u_{qit}$$

Example: if producer i sets $MR_{it} = MC_{it}$,

$$\phi_{qi} = \left[\frac{\partial \log MC_{it}}{\partial \log Q_{it}} \right]^{-1}$$

u_{qit} is negative of shock to $\log MC_{it}$

$\mathbf{b}_{qi}$ reflects serial correlation of MC_{it} shocks

Demand curve of country j

$$c_{jt} = \phi_{cj} p_t + \mathbf{b}'_{cj} \mathbf{x}_{t-1} + u_{cjt}$$

ϕ_{cj} = country j short-run demand elasticity

u_{cjt} = demand shock for country j

Inventory demand

$$v_t = \phi_v p_t + \mathbf{b}'_v \mathbf{x}_{t-1} + u_{vt}$$

This equals difference between
global production and consumption

$$v_t = \sum_{i=1}^n s_{qi} q_{it} - \sum_{j=1}^m s_{cj} c_{jt}$$

v_t also includes measurement error

Structural model:

$$q_{it} = \phi_{qi} p_t + \mathbf{b}'_{qi} \mathbf{x}_{t-1} + u_{qit} \quad i = 1, \dots, n$$

$$\text{or } \mathbf{q}_t = \underbrace{\boldsymbol{\phi}_q}_{(n \times 1)} p_t + \underbrace{\mathbf{B}_q}_{(n \times k)} \mathbf{x}_{t-1} + \underbrace{\mathbf{u}_{qt}}_{(n \times 1)}$$

$$c_{jt} = \phi_{cj} p_t + \mathbf{b}'_{cj} \mathbf{x}_{t-1} + u_{cjt} \quad j = 1, \dots, m$$

$$\text{or } \mathbf{c}_t = \underbrace{\boldsymbol{\phi}_c}_{(m \times 1)} p_t + \underbrace{\mathbf{B}_c}_{(m \times k)} \mathbf{x}_{t-1} + \underbrace{\mathbf{u}_{ct}}_{(m \times 1)}$$

$$\mathbf{s}'_q \mathbf{q}_t - \mathbf{s}'_c \mathbf{c}_t = \phi_v p_t + \mathbf{b}'_v \mathbf{x}_{t-1} + u_{vt}$$

$$\underset{(1 \times N)}{\mathbf{y}'_t} = \begin{bmatrix} \underset{(1 \times n)}{\mathbf{q}'_t} & \underset{(1 \times m)}{\mathbf{c}'_t} & \underset{(1 \times 1)}{p_t} \end{bmatrix}$$

$$\underset{(1 \times N)}{\mathbf{u}'_t} = \begin{bmatrix} \underset{(1 \times n)}{\mathbf{u}'_{qt}} & \underset{(1 \times m)}{\mathbf{u}'_{ct}} & \underset{(1 \times 1)}{u_{vt}} \end{bmatrix}$$

$$\mathbf{A}\mathbf{y}_t = \mathbf{B}\mathbf{x}_{t-1} + \mathbf{u}_t$$

$$\underset{(N \times N)}{\mathbf{A}} = \begin{bmatrix} \mathbf{I}_n & \mathbf{0}_{nm} & -\phi_q \\ \mathbf{0}_{mn} & \mathbf{I}_m & -\phi_c \\ \mathbf{s}'_q & -\mathbf{s}'_c & -\phi_v \end{bmatrix} \quad \underset{(N \times k)}{\mathbf{B}} = \begin{bmatrix} \mathbf{B}_q \\ \mathbf{B}_c \\ \mathbf{b}'_v \end{bmatrix}$$

Given any value for $\mathbf{u}_t$, there exists a value of $p_t, \mathbf{q}_t, \mathbf{c}_t$ for which all N equations hold. Identification comes from assumptions about correlations between the structural shocks in $\mathbf{u}_t$

Granular instrumental variables (Gabaix and Koijen, JPE forthcoming)

Example: suppose supply shocks are uncorrelated with demand shocks,

$$E(\mathbf{u}_{qt} \mathbf{u}'_{ct}) = \mathbf{0}_{nm},$$

and elasticities are homogeneous across countries:

$$\begin{array}{cc} \phi_q = \phi_q \mathbf{1}_n & \phi_c = \phi_c \mathbf{1}_m \\ \begin{smallmatrix} (n \times 1) & (1 \times 1)(n \times 1) \end{smallmatrix} & \begin{smallmatrix} (m \times 1) & (1 \times 1)(m \times 1) \end{smallmatrix} \end{array}$$

Let $\mathbf{s}_q$ be the $(n \times 1)$ vector of global production shares.

Let $\mathbf{w}_q$ be any other $(n \times 1)$ vector for which $\mathbf{w}_q' \mathbf{1}_n = 1$.

$$\mathbf{q}_t = \phi_q \mathbf{1}_n p_t + \mathbf{B}_q \mathbf{x}_{t-1} + \mathbf{u}_{qt}$$

$$(\mathbf{s}_q - \mathbf{w}_q)' \mathbf{q}_t = (\mathbf{s}_q - \mathbf{w}_q)' \mathbf{B}_q \mathbf{x}_{t-1} + (\mathbf{s}_q - \mathbf{w}_q)' \mathbf{u}_{qt}$$

$$(\mathbf{s}_q - \mathbf{w}_q)' \mathbf{q}_t = (\mathbf{s}_q - \mathbf{w}_q)' \mathbf{B}_q \mathbf{x}_{t-1} + (\mathbf{s}_q - \mathbf{w}_q)' \mathbf{u}_{qt}$$

Conclusion:

$(\mathbf{s}_q - \mathbf{w}_q)' \mathbf{q}_t$ is uncorrelated with $\mathbf{u}_{ct}$.

Could estimate ϕ_c by IV

$$\mathbf{w}_c' \mathbf{c}_t = \phi_c p_t + \tilde{\mathbf{B}}_c \mathbf{x}_{t-1} + \tilde{u}_{ct}.$$

Instruments: $(\mathbf{s}_q - \mathbf{w}_q)' \mathbf{q}_t$ and $\mathbf{x}_{t-1}$

$\mathbf{w}_c$ is any $(m \times 1)$ vector with $\mathbf{w}_c' \mathbf{c}_t = 1$.

Example:

$$\mathbf{w}_q = n^{-1} \mathbf{1}_n$$

$(\mathbf{s}_q - \mathbf{w}_q)' \mathbf{q}_t$ is difference between share-weighted and arithmetic average production.
This is the granular instrument insight of Gabaix and Koijen (JPE forthcoming).

Could also find supply elasticity ϕ_q
from regression of $\mathbf{w}'_q \mathbf{q}_t$ on p_t and $\mathbf{x}_{t-1}$
using $(\mathbf{s}_c - \mathbf{w}_c)' \mathbf{c}_t$ and $\mathbf{x}_{t-1}$ as
instruments.

Maximum likelihood estimation:

$$\mathbf{u}_t \sim N(\mathbf{0}, \mathbf{D})$$

$$\mathbf{D}_{(N \times N)} = \begin{bmatrix} \mathbf{D}_q_{(n \times n)} & \mathbf{0}_{nm} & \mathbf{0}_{n1} \\ \mathbf{0}_{mn} & \mathbf{D}_c_{(m \times m)} & \mathbf{0}_{m1} \\ \mathbf{0}_{1n} & \mathbf{0}_{1m} & \sigma_v^2_{(1 \times 1)} \end{bmatrix}$$

Define

$$\hat{\Pi} = \left[\sum_{t=1}^T \mathbf{y}_t \mathbf{x}_{t-1}' \right] \left[\sum_{t=1}^T \mathbf{x}_{t-1} \mathbf{x}_{t-1}' \right]^{-1}$$

$$\begin{matrix} \hat{\boldsymbol{\epsilon}}_t & = & \mathbf{y}_t - \hat{\Pi} \mathbf{x}_{t-1} & = & \begin{bmatrix} \hat{\boldsymbol{\epsilon}}_{qt} \\ \hat{\boldsymbol{\epsilon}}_{ct} \\ \hat{\boldsymbol{\epsilon}}_{pt} \end{bmatrix} \\ (N \times 1) & & & & \begin{matrix} (n \times 1) \\ (m \times 1) \\ (1 \times 1) \end{matrix} \end{matrix}$$

$$\hat{\boldsymbol{\epsilon}}_{vt} = \mathbf{s}_q' \hat{\boldsymbol{\epsilon}}_{qt} - \mathbf{s}_c' \hat{\boldsymbol{\epsilon}}_{ct}$$

Proposition 2: FOC for MLE are

$$\hat{\phi}_c = \frac{\sum_{t=1}^T \tilde{z}_{ct} \tilde{c}_t}{\sum_{t=1}^T \tilde{z}_{ct} \hat{\epsilon}_{pt}}$$

$$\tilde{c}_t = \hat{\mathbf{w}}_c' \hat{\boldsymbol{\epsilon}}_{ct} \quad \hat{\mathbf{w}}_c' = \mathbf{1}_m' \hat{\mathbf{D}}_c^{-1} / (\mathbf{1}_m' \hat{\mathbf{D}}_c^{-1} \mathbf{1}_m)$$

$$\hat{\mathbf{D}}_c = T^{-1} \sum_{t=1}^T \left(\hat{\boldsymbol{\epsilon}}_{ct} - \hat{\phi}_c \mathbf{1}_m \hat{\epsilon}_{pt} \right) \left(\hat{\boldsymbol{\epsilon}}_{ct} - \hat{\phi}_c \mathbf{1}_m \hat{\epsilon}_{pt} \right)'$$

$$\tilde{z}_{ct} = -(\mathbf{s}_q - \hat{\mathbf{w}}_q)' \hat{\boldsymbol{\epsilon}}_{qt} - (\tilde{q}_t - \hat{\phi}_q \hat{\epsilon}_{pt}) + (\hat{\epsilon}_{vt} - \hat{\phi}_v \hat{\epsilon}_{pt})$$

$$\tilde{q}_t = \hat{\mathbf{w}}_q' \hat{\boldsymbol{\epsilon}}_{qt} \quad \hat{\mathbf{w}}_q' = \mathbf{1}_n' \hat{\mathbf{D}}_q^{-1} / (\mathbf{1}_n' \hat{\mathbf{D}}_q^{-1} \mathbf{1}_n)$$

$$\hat{\mathbf{D}}_q = T^{-1} \sum_{t=1}^T \left(\hat{\boldsymbol{\epsilon}}_{qt} - \hat{\phi}_q \mathbf{1}_n \hat{\epsilon}_{pt} \right) \left(\hat{\boldsymbol{\epsilon}}_{qt} - \hat{\phi}_q \mathbf{1}_n \hat{\epsilon}_{pt} \right)'$$

Analogous FOC for $\hat{\phi}_q$ and $\hat{\phi}_v$

$$\hat{\phi}_q = \frac{\sum_{t=1}^T \tilde{z}_{qt} \tilde{q}_t}{\sum_{t=1}^T \tilde{z}_{qt} \hat{\epsilon}_{pt}}$$

$$\tilde{z}_{qt} = (\mathbf{s}_c - \hat{\mathbf{w}}_c)' \hat{\epsilon}_{ct} + (\tilde{c}_t - \hat{\phi}_c \hat{\epsilon}_{pt}) + (\hat{\epsilon}_{vt} - \hat{\phi}_v \hat{\epsilon}_{pt})$$

$$\hat{\phi}_v = \frac{\sum_{t=1}^T \tilde{z}_{vt} \hat{\epsilon}_{vt}}{\sum_{t=1}^T \tilde{z}_{vt} \hat{\epsilon}_{pt}}$$

$$\hat{\epsilon}_{vt} = \mathbf{s}'_q \hat{\epsilon}_{qt} - \mathbf{s}'_c \hat{\epsilon}_{ct}$$

$$\begin{aligned} \tilde{z}_{vt} = & (\mathbf{s}_c - \hat{\mathbf{w}}_c)' \hat{\epsilon}_{ct} - (\mathbf{s}_q - \hat{\mathbf{w}}_q)' \hat{\epsilon}_{qt} \\ & - (\tilde{q}_t - \hat{\phi}_q \hat{\epsilon}_{pt}) + (\tilde{c}_t - \hat{\phi}_c \hat{\epsilon}_{pt}) \end{aligned}$$

Iterated 3SLS

$$\hat{\phi}_c^{(1)} = \frac{\sum_{t=1}^T \tilde{z}_{ct}^{(1)} \tilde{c}_t^{(1)}}{\sum_{t=1}^T \tilde{z}_{ct}^{(1)} \hat{\epsilon}_{pt}}$$

$$\tilde{c}_t^{(1)} = \mathbf{s}_c' \hat{\boldsymbol{\epsilon}}_{ct} \quad \tilde{z}_{ct}^{(1)} = (n^{-1} \mathbf{1}_n - \mathbf{s}_q)' \hat{\boldsymbol{\epsilon}}_{qt}$$

$$\hat{\mathbf{D}}_c^{(1)} = T^{-1} \sum_{t=1}^T \left(\hat{\boldsymbol{\epsilon}}_{ct} - \hat{\phi}_c^{(1)} \mathbf{1}_m \hat{\epsilon}_{pt} \right) \left(\hat{\boldsymbol{\epsilon}}_{ct} - \hat{\phi}_c^{(1)} \mathbf{1}_m \hat{\epsilon}_{pt} \right)'$$

$$\tilde{c}_t^{(2)} = \hat{\mathbf{w}}_c^{(2)'} \hat{\boldsymbol{\epsilon}}_{ct}$$

$$\hat{\mathbf{w}}_c^{(2)'} = \mathbf{1}_m' \left(\hat{\mathbf{D}}_c^{(1)} \right)^{-1} \div \left[\mathbf{1}_m' \left(\hat{\mathbf{D}}_c^{(1)} \right)^{-1} \mathbf{1}_m \right]$$

Comparison of plain-vanilla granular IV (step 1 of 3SLS) and MLE (iterate on 3SLS to convergence)

Parameter	IV	MLE
Demand elasticity ϕ_c	-0.106 (0.252)	-0.130 (0.026)
Supply elasticity ϕ_q	-3.699 (7.717)	0.054 (0.009)
Inventory demand elasticity ϕ_v		-0.373 (0.052)

(standard errors in parentheses)

Likelihood ratio test rejects the model's 21 overidentifying assumptions. A more general model with heterogeneous elasticities is also rejected.

Reason: there do not exist (4×1) vectors ϕ_q and ϕ_c for which

$$T^{-1} \sum_{t=1}^T (\hat{\epsilon}_{qt} - \phi_q \hat{\epsilon}_{pt})(\hat{\epsilon}_{ct} - \phi_c \hat{\epsilon}_{pt})' \simeq \mathbf{0}_{nm}.$$

Supply shocks $\mathbf{u}_{qt}$ and demand shocks $\mathbf{u}_{ct}$ appear to be correlated.

We allow a single global factor on which both $\mathbf{u}_{qt}$ and $\mathbf{u}_{ct}$ can load without restriction.

Seems to be response of Saudi and OPEC production to global demand.

Proposed model:

ϕ_q and ϕ_c unrestricted (4×1) vectors

$$\mathbf{D} = E(\mathbf{u}_t \mathbf{u}_t') =$$

$$\begin{bmatrix} \mathbf{h}_q \mathbf{h}_q' + \Sigma_q & \mathbf{h}_q \mathbf{h}_c' & \mathbf{0}_{n1} \\ \mathbf{h}_c \mathbf{h}_q' & \mathbf{h}_c \mathbf{h}_c' + \gamma_c \gamma_c' + \Sigma_c & \mathbf{0}_{m1} \\ \mathbf{0}_{1n} & \mathbf{0}_{1m} & \sigma_v^2 \end{bmatrix}$$

$\mathbf{h}_q, \mathbf{h}_c, \gamma_c$ are (4×1) vectors

Σ_q and Σ_c are diagonal (4×4) matrices

Model has 16 overidentifying

restrictions that are not rejected.

Inventory demand	-0.355	-0.187	

Conclusion

- If correlations between supply and demand shocks can be described with low-order factor structure, can use correlations between price and country-specific production and consumption to estimate key elasticities.
- Next step: use regularization to apply to larger numbers of producers and consumers.
