## Problem Set 5

It's OK to work together on problem sets.

## 1. Starr's General Equilibrium Theory, problem 7.2.

2. Consider an Edgeworth Box for two households. The two goods are denoted $\mathrm{x}, \mathrm{y}$. The households have identical preferences:

$$
\begin{aligned}
& (x, y) \succ\left(x^{\prime}, y^{\prime}\right) \text { if } 3 x+y>3 x^{\prime}+y^{\prime}, \quad \text { or } \\
& (x, y) \succ\left(x^{\prime}, y^{\prime}\right) \text { if } 3 x+y=3 x^{\prime}+y^{\prime} \text { and } x>x^{\prime} \text {. } \\
& (x, y) \sim\left(x^{\prime}, y^{\prime}\right) \text { only if }(x, y)=\left(x^{\prime}, y^{\prime}\right) .
\end{aligned}
$$

They have identical endowments of $(10,10)$. Demonstrate that there is no competitive equilibrium. Is this example a counterexample to Theorem 7.1 (does it demonstrate that Theorem 7.1 is false?) ? Explain.
3. Consider a small economy, with two goods and three households. The two goods are denoted $\mathrm{x}, \mathrm{y}$. The households have identical preferences described by the utility function
$u(x, y)=\sup [x, y]$. Where sup indicates the supremum or maximum of the two arguments. Demonstrate that these preferences are nonconvex; they do not fulfill Starr's General Equilibrium Theory assumptions C.VI or CVII.

The households have identical endowments of $(10,10)$. Demonstrate that there is no competitive equilibrium in this economy [Hint: Show that price vector $(1 / 2+\varepsilon, 1 / 2-\varepsilon), \varepsilon>0$, cannot be an equilibrium; similarly for $(1 / 2-\varepsilon, 1 / 2+\varepsilon)$; and finally $(1 / 2,1 / 2)$. That pretty well takes care of it.]
4. Starr's General Equilibrium Theory problem 7.6, parts (i), (ii). Part (iii) is rewritten below. "competitive equilibria" means "competitive general equilibria."
(iii) Assuming in addition continuity of $\tilde{Z}(\mathrm{p}), \mathrm{Q}$ has a fixed point $\mathrm{p}^{*} \in \mathrm{P}$ so that $\mathrm{Q}\left(\mathrm{p}^{*}\right)=\mathrm{p}^{*}$. Does this prove that under these assumptions the economy has a competitive general equilibrium?
5. Let $\mathrm{f}: \mathrm{P} \rightarrow \mathrm{P}$, f continuous. Define $\mathrm{Z}(\mathrm{p})=\mathrm{f}(\mathrm{p})-\left[\frac{\mathrm{p} \cdot \mathrm{f}(\mathrm{p})}{\mathrm{p} \cdot \mathrm{p}}\right] \mathrm{p}$. The term in square brackets is just a scalar multiplying the vector $p$. Show that $p \cdot Z(p)=0$. Z is a continuous function, $\mathrm{Z}: \mathrm{P} \rightarrow \mathrm{R}^{\mathrm{N}}$. Why? Assume there is a competitive
equillibrium price vector $\mathrm{p}^{*}$ so that $\mathrm{Z}\left(\mathrm{p}^{*}\right)=0$ (the zero vector; ignore excess supplies of free goods). Is $p^{*}$ also a fixed point of $f$ so that $f\left(p^{*}\right)=p^{*}$ ? Review Theorem 11.2 in Starr’s General Equilibrium Theory to see what you've demonstrated.
